This document is a research roadmap on urban freight and logistics delivered jointly by ERTRAC, the European Road Transport Research Advisory Council, and ALICE, Alliance for Logistics Innovation through Collaboration in Europe. The goal of the roadmap is to identify research priorities related to urban freight delivery, returns and urban logistics to improve the efficiency, sustainability and security of this activity. The contents will contribute to the definition of research programmes addressing the main stakeholders of the sector (cities, industry, retail, logistics services providers), including Horizon 2020, the European Framework Programme for Research and Innovation for 2014-2020.

The scope of the roadmap is urban freight transport, defined as all movements of goods into, out of, through or within the urban area, made by light or heavy vehicles, including:

- Delivery of goods (business and home).
- Service transport and demolition traffic.
- Shopping trips made by private households.
- Reverse logistics for waste removal and for returns management.
- Service vans for maintenance, supply and removal of parts.

The vision is to achieve a full integration of freight flows in cities’ operations and activities that allow citizens to access the goods they require and the goods to access the citizens, while at the same time supporting sustainable development. Research areas identified aim to:

- Increase energy efficiency, which can be achieved by improving the efficiency of the whole urban logistics system added to the expected gains in the energy efficiency of vehicles.
- Improve the urban environment by increasing air quality and reducing noise.
- Increase customer satisfaction by delivering the goods on time and improving the reliability of the system.
- Increase safety and security reducing injuries and fatalities and also cargo lost or damage.

When preparing the roadmap, the following issues were taken into account:

- Concentration of population in cities (72% EU population - live in cities, towns and suburbs, 80% in 2020).
- Urban freight as an important traffic component in cities (10 to 15% of vehicle equivalent miles).
- Very low load factors for delivery vehicles in cities (e.g. 38% for vans in London).
- Urban freight being responsible for 25% of urban transport related CO₂ emissions and 30 to 50% of other transport related pollutants (Particulate matter, Nitrogen Oxide).
- Urban freight service companies generally being very small (85% of short distance truck companies have less than five employees).
- Urban freight accounting for a significant part of ambient noise.
- Changing urban freight patterns due to teleworking, ageing population, more densely populated urban areas, growth of e-Commerce.
- European Policy for zero CO₂ emissions in cities by 2030.
The roadmap includes research challenges in five areas of intervention with the following expected impacts:

ERTRAC, the European Road Transport Advisory Council, and ALICE, Alliance for Logistics Innovation through Collaboration in Europe, have identified the need to pool resources and develop jointly a research roadmap on urban freight and logistics. It complements ERTRAC work on urban mobility, which so far had mostly focused on passengers transport and only marginally addressed freight and ALICE roadmaps on: 1. Sustainable and Secure Supply Chains; 2. Corridors, Hubs and Synchronodality; 3. Information Systems for Interconnected Logistics and 4. Global Supply Network Coordination and Collaboration. This roadmap fills the gap and covers an activity which at the same time is essential for the competitiveness of the European economy and important for the efficiency of the transport system. It is estimated that urban freight represents 10 to 15% of vehicle equivalent miles travelled on city streets and 2.5% of the employed urban workforce. Urban freight transport mainly represents road based transport and will continue to do so.

The goal of the roadmap is to identify research priorities related to urban freight, returns and urban logistics and to contribute to the definition of research programs for the actors of the sector, including Horizon 2020, the European Programme for Research and Innovation.

The implementation of the research topics and activities identified in this document are required to achieve the objectives of the ERTRAC and ALICE Strategic Research Agendas.
Experts from all important stakeholders group involved in urban freight operations and research activities have been invited to contribute to this work.

In order to best relate to the societal goal of the ERTRAC Strategic Research Agenda, this roadmap proposes additional indicators and guiding objectives better fit for the urban freight sector.

The research topics identified in the roadmap are for instance expected to contribute to other societal goals, including reducing the impact on the local environment (air quality and noise).

This roadmap is a living document that covers higher research priorities in the field of urban logistics identified so far. New concepts and elements that may impact urban freight will need to be considered in future revisions of this roadmap. Specifically, the impact of e-commerce and the potential implementation of an ALICE vision on Physical Internet and its implications on urban freight will need to be further assessed in near future.

* Versus 2010 baseline
1.1 Guiding objectives for 2030 for urban freight

1.1.1 Decarbonization

As in the ERTRAC Strategic Research Agenda, the roadmap recommends to use **energy efficiency as indicator for decarbonisation, measured in tkm/kWh**. Energy efficiency gains can be achieved by improving the efficiency of the whole urban freight and logistics system added to the expected gains in the energy efficiency of vehicles.

Gains on the vehicle side are expected to come from the increased efficiency of ICE vehicles but also from the progressive deployment of alternative fuels vehicles, in particular, but not only, electric vehicles for urban freight. This means that the potential gains in energy efficiency of the vehicles performing urban freight transport will also depend on the evolution of the urban transport system as a whole and more specifically though not uniquely, of the urban freight system. Indeed, the introduction of electric vehicles is conditioned by the deployment of a charging infrastructure, probably including fast charging points, potentially shared in some cases with public transport vehicles. It will also depend on the ability to progressively deploy solutions enabling the consolidation of the delivery of goods, which would reduce the comparative additional cost of using EVs for freight delivery.

Energy efficiency will also be improved through the overall improvement of the efficiency of the urban freight system. Solutions enabling to increase the load factor of vehicles or load units, to reduce the number of km driven per kg/good delivered, reducing empty runs to increase the effectiveness of deliveries, to decrease empty trips and to reduce the number of shopping trips in particular, all contribute to increase the energy efficiency of the system.

The expected impacts of the research topics identified in the document indicate how they are expected to contribute to more energy efficiency.

---

1.1.2 Local environment

The various contributors to this document stress the importance to set the improvement of the impact of urban freight activity on the local environment as one of the guiding objective for this document.

It is expected that the research topics identified in the roadmap will contribute to the improvement of the air quality in European cities. It should be noted that the factors contributed to local air pollution can vary significantly from cities to cities, and that the relative contribution of transport to air pollution in cities varies as well. It is therefore not possible to set a target for the improvement of air quality.

This topics proposed in the roadmap are expected to enable a reduction of the concentration of particulates (PM) in the air as well as of the emission of NOx from the road transport sector. This can be achieved by a reduction of the emissions of the vehicles themselves related to the improvement of their emission performance as well as to the evolution of their operation in the urban environment. For instance their better integration in traffic management strategy integrating local emissions as a parameter could lead to reduced emissions from the freight fleets.

It is considered that if we compare a city with a fleet including only euro 6 vehicles in 2030, to the same city in 2010 composed by an average euro 4 fleet, the reduction of emissions from the vehicles, all things being equal, could be of 80% for PM and 90% for NOx.

This only gives a very partial picture of what could be the evolution of the actual emissions from urban freight. This also depends on the evolution of the volume of goods transported, of the average number of km per goods (weight/volume) transported, etc. It also depends on the penetration of vehicle technology in the market, in particular electric vehicles, which itself depends also on the system as explained above.

It can be stressed though that the greater the efficiency in the urban delivery system and in logistics operation, the lower the emissions per units transported are expected to be.

Another important local emission to which urban freight contributes significantly is noise. Lowering noise emissions from delivery activities is important to reduce its impact on the health of the citizens and to enable the generalisation of night delivery whenever and wherever it can be introduced in the logistic chain. This requires lowering the noise of the vehicles and auxiliaries but also continuing to lower the noise related to the handling of the goods and loading and unloading activities.
1.1.3 Reliability

The objective to improve the reliability of the road transport system has been translated in the scope of this roadmap, in the improvement of the effectiveness of deliveries in the urban environment. Deliveries are considered effective when the good is delivered and that there is a person or place where it can be delivered at the anticipated delivery point.

For B2B, the % of effective deliveries already reached a sustainable target close to 95%. It is estimated that 70% to 75% of deliveries are successful for B2C in the urban environment.

The objective should be to rely upon the increasing efficiency of the logistics and the urban delivery system to tend towards 100%. The rapid and very important increase of e-commerce is a challenge in this respect. It should be supported by initiatives which could be enabled by the research topics identified in the roadmap and the application to just in time policies.

1.1.4 Safety and Security

There is a growing concern about fatalities and injuries involving commercial vehicles and vulnerable road users (VRUs) in the urban environment. It is therefore proposed to focus on this indicator relating to road safety.

While the European Union has kept ambitious road safety goals, some cities are moving towards the definition of a vision zero. There are important efforts, from the research community, focusing on VRUs and commercial vehicles, requiring strong political support, addressing all the dimensions of the problem, infrastructure, vehicles and people’s behaviour. It is therefore expected that they can lead to a very significant reduction of this specific group of fatalities and injuries possibly reaching 90% by 2030 (some cities are already taking actions towards this objective).

An efficient urban freight transport system must rely on secure deliveries and a minimum amount of cargo lost to theft and damages. The objective should be to tend to reducing to the maximum this amount and it can be expected that with progress in research initiatives and systems will be implemented allowing to decrease by close to 90% the amount of cargo lost to theft and damages.

For each of the research challenges identified in the document, the expected direct impacts of the projects are listed. These impacts contribute to achieving these objectives. Among those impacts are important policy objectives such as the reduction of congestion. Their further definition may be the focus of some further work.
1.2

Background

1.2.1

A key activity in an increasingly urbanized Europe

It is important to consider this roadmap bearing in mind some facts on cities in Europe and urban freight transport in these cities.

The European Union is a largely urban continent. “Today, approximately 359 million people - 72% of the total EU population - live in cities, towns and suburbs.”3 Although the speed of transformation has slowed down, the share of the urban population continues to grow and will reach 80% by 2020. “Europe is characterised by a polycentric and less concentrated urban structure compared to, for instance, the USA or China. There are 26 cities of more than 1 million inhabitants and additional 373 cities of more than 100,000 inhabitants in the European Union, representing around 165 million people.”4 The demographic evolution of the cities on the continent varies greatly. Some such as London or Brussels are expecting a very significant growth of their population in the coming decade while others are shrinking.

As economic centres, cities are not only the place of delivery of goods but also ship them: outgoing freight represents 20 to 25% of truck-km in urban areas, incoming freight 40 to 50%, and the rest originates from and is delivered within the city. Waste transport also represents an important activity in urban logistics. 3 to 5% of urban land is devoted to freight transport and logistics.

3. Annex of Cities issue paper, the urban agenda, European Commission, 2014
4. Ibid
1.2.2

Urban freight: a responsive and flexible sector

Urban logistics is an extremely flexible activity. It adapts to current profound changes in demographics, urban economy, new shopping and distribution behaviours, new demands from consumers and businesses.

Transport companies providing urban freight services are generally very small. In Europe, 85% of short distance truck companies have less than five employees. They usually work as subcontractors of bigger umbrella organizations but integration is not always achieved. Every year €100 billion, or 1% of the EU GDP, are lost to the European economy as a result of delays and pollution related to urban traffic. Urban freight is also characterised by a very significant informal sector, the so-called white vans, estimated in many countries to represent around 25%-30% of urban deliveries.

1.2.3

A significant contributor to the negative impact of transport on the urban environment

In Europe, urban freight is responsible for 25% of urban transport related CO₂ emissions and 30 to 50% of other transport related pollutants (Particulate matters, Nitrogen Oxide, etc.).

In large cities, while commercial vehicles represent a small proportion of the traffic, they are involved in a majority of accidents involving also vulnerable road users.

Urban freight transport accounts for a significant part of ambient noise in cities and mainly causes discomfort to people during the night (disturbed sleep,...), when no appropriate measures are taken.

These negative impacts of freight activities influence the attractiveness of the city and its liveability.

The load factors for delivery vehicles in cities are very low, e.g. Transport for London reports an average load factor for vans in London of approximately 38%.

6. According to Transport for London for instance, between 2008 and 2012 53% of cycling fatalities involved HGVs in London
1.2.4

Political objectives anticipating technological developments and the implementation of innovation

The white paper on transport and the Horizon 2020 sets ambitious targets for the reduction of CO₂ emissions from city logistics. The White Paper sets the goal to achieve “essentially CO₂-free city logistics in major urban centres by 2030 with the aim of an ‘essentially carbon free’ city logistic by 2030.”

All these facts have led over the past fifteen years to a significant number of research and innovation initiatives to improve the efficiency of urban freight which have not, so far, resulted in a broad gain in efficiency in the sector (annex).

When trying to tackle the above mentioned challenges, we should consider urban logistics as a part of a geographically broader logistics activity. Urban logistics is where most supply chains having the end consumer as its primary target end. Therefore, a holistic approach should be followed to understand what can be done upstream the supply chain to optimize urban logistics. But, the peculiarities of cities, and the differences (in legislation, regulation, infrastructure network, urban configuration, social habits, etc.) call also for a focus on the urban logistics itself. Different business models, new processes and technologies should be researched and implemented.

To become more efficient and better answer the needs of citizens and businesses, urban transport system are becoming more integrated. This also leads to the need for a better integration of freight activities in the urban transport system and beyond in the urban environment. Such an evolution should allow more consideration for intermodal and multimodal solutions for urban freight.

The evolution of urban freight transport will be influenced by the deployment of vehicles technologies in the coming years. Research and innovation will have to identify how new technologies will influence urban freight and how to best take advantage of them.

The electrification of road transport for instance is an important factor to take into account. The pressure for improving air quality in urban areas is likely to be an important driver for the deployment of electric delivery vehicles. This will mean in many cases that goods will be transferred to these electric vehicles in or around the city. It will be important to assess how this transfer can be integrated in the logistic chain and how it can also represent an opportunity for cooperation and consolidation.

More and more vehicles will be connected between themselves and with infrastructure managers, using C-ITS for instance, which will enable significant improvement in the management of urban freight for greater efficiency. It should also be understood how automation of vehicles and of some operations can be best used for urban freight.

Finally, one should not forget that freight transport serves human activities. The evolution of the city and of our lifestyles will have a significant impact on urban freight patterns. Factors such as the development of teleworking, an ageing population, the evolution of land use towards more densely populated urban areas, or the growth of e-commerce will have a direct and potentially very significant impact on urban freight patterns.
1.3 Scope

Urban Freight transport is defined as all movements of goods in to, out from, through or within the urban area made by light or heavy vehicles, including also service transport, construction material transport and demolition traffic, shopping trips made by private households and reverse logistics for waste removal and also for returns management7 thus excluding all personal movements with the exception of shopping trips.

The inclusion of shopping trips in the scope of the roadmap implies that interactions with passenger transport are very important and should be considered. However, vehicles not designed specifically for freight transport, such as passenger cars, are outside the scope of the roadmap.

Construction material transport and demolition traffic are relevant traffic components in urban areas. Specific topics on how optimize and reduce impacts of this type of traffic will be addressed and analyzed in this roadmap.

Other traffic movements related to freight movements, such as maintenance and service vans for the supply and removal of parts are considered.

The scope of the roadmap covers all components of the system:** vehicles, infrastructure and services.**

It should cover the efficient integration of urban freight delivery in the urban transport system, and the integration of urban logistics in broader scale logistics operations.

The roadmap identifies data collection and knowledge building on urban logistics as the first step for a relevant urban logistics research agenda.

7. Maria E. Lindholm, Enabling Sustainable Development of Urban Freight from a local authority perspective, Chalmers University
1.4

Overview of relevant projects and initiatives (Annex 2)

The roadmap includes in Annex 2 a list of the most relevant national and European projects which have covered urban freight research since FP5. Only projects which have a significant share of their activity relevant for the urban delivery system are listed.

The goal of this list is to help creating a picture of the current state of the art with a list of reference activities.

It should also help to better assess gaps and research needs, as well as to understand the reasons for failure when project proposals have not survived over project life or project public funding.

This tool can be updated and used to monitor the implementation of the roadmap.

It should also be used for the update of the roadmap and to further assess gaps and research needs.
Complementarities with other ALICE and ERTRAC roadmaps

This document takes into account relevant roadmaps developed in the framework of the European Green Cars Initiative, EGCI, Logistics for Life project, L4L, and the European Road Transport Research Advisory Council, ERTRAC and CIVITAS position paper. It is also aware of the two newly created centres of excellence in urban freight research involving several European institutes (www.vref.se).

It is considering initiatives such as the JPI Urban Europe and Smart Cities EIP.

Among other references, the preparation of the roadmap relies upon the work done in the CAPIRE project, in particular its urban freight roadmap, and the EGCI roadmap on logistics.

Urban freight is fully part of the urban transport system. There is therefore a strong need to ensure the coherence with the ERTRAC roadmap on the integration of the urban mobility network. This materialises in particular in topics related to freight traffic, and to the exploration of potential synergies between passenger and freight transport at the urban level.

There are important challenges related to the use of land for urban freight, and the location of logistics activity in and around the urban environment. This document is therefore providing a complementary approach on this issue to some of the research topics identified in the ERTRAC document on land use and transport.

This roadmap will be complemented with other ALICE roadmaps (Figure 2). Specifically, the roadmap on Corridors, Hubs and Synchromodality will cover the link between long distance transport and the last mile. To elaborate this roadmap, ALICE, ERRAC, ERTRAC and WATERBORNE are joining efforts to achieve a holistic end-to-end co-modal approach.

ALICE roadmaps on Information Systems for Interconnected Logistics and Supply Network Coordination and Collaboration will complement specific research needs in those areas keeping an eye towards the implementation of the long term vision on the Physical Internet.
This also requires ensuring the coherence of the research related to land use and the road infrastructure described in this roadmap with the joint ETP roadmap on road infrastructure.

The need to gain efficiency and contribute to both, the decarbonisation of road transport and the improvement of the local environment requires carrying research on cleaner vehicles for urban logistics. It is important to note that most of the relevant research topics on this matter are identified in the joint ERTRAC/EPOSS/Smartgrid roadmap on the electrification of road transport and ERTRAC roadmaps on an infrastructure for green vehicles.

Finally, the roadmap has to be coherent within the frame of the ALICE ETP work. Urban Logistics research has to provide other logistics research areas with the necessary completeness to guarantee an efficient and sustainable supply chain right to the end and whenever it is necessary to remove goods or materials, in general (like waste) upstream for recycling, reuse, refurbishment or destruction.
Although urban freight transport is broadly recognized as a fundamental part of economic trade and impacts on cities’ life severely (contributing to worsening congestion, air quality and noise) there is no satisfactory and comprehensive qualitative and quantitative evaluation of those impacts. This is partly due to the difficulties to measure freight traffic separately from the rest of traffics. Polls and surveys are more difficult also given the many different types of freight traffics, service demands, sizes of companies acting in urban deliveries, and types of clients. Fierce competition among service providers opposes the need and opportunities to share and communicate data. Collaborative transportation systems have become an increasingly popular practice due to the crisis. Collaborative transportation is appearing as a good city logistics alternative to classical urban consolidation centres. The concept of cooperation & competition and data sharing still requires further development. There is therefore a strong need to acquire targeted consistent and homogeneous data in order to properly assess the problem and monitor the evolution of the different Key Performance Indicators as different sets of measurements are adopted. It is expected that better data, knowledge and information will make it easier to identify opportunities for improvement.
Cities are complex environments which have inherited a certain structure (both in terms of social, economic, political and infrastructural conditions) based on a particular historical evolution. Solutions easy to replicate, or, at least, potentially replicable, across cities are very tempting and useful, since previous efforts can be reutilized. However, cities have proven to be almost unique and solutions very difficult to replicate. The definition of KPIs and of a benchmarking tool will allow simplifying the process of replication by identifying potential similarities among cities and thus permitting an adequate subset of previously demonstrated tools to apply to a particular city or district. Even if entirely new solutions have to be developed, the KPIs will show the real impact of those new solutions and to what extent they can be replicated in other cities.

The development and use of modelling tools is necessary to better understand the economics and behaviours, and to assess the impact of a number of variables, including policy measures, on the KPIs. For this purpose as well, data and information collection are essential.

Demand triggers services and one of the difficulties and complexities linked to urban logistics is the different demands that generate so many different types of urban logistics services. Understanding the demand and, even more, being able to anticipate or influence it would help creating more efficient services.

Innovative urban distribution concepts have already been developed, often within the context of research projects. Many of these real-life implementations die a silent death shortly after project (and the funding) ends. It is suggested that these solutions tend to address the objectives of only one or two stakeholders whilst urban freight is characterized by the large number of stakeholders with often diverging objectives. During a project, this can be camouflaged by the commitment of the actors participating in the project. Once the project is finished, however, the lack of overall stakeholder support and the real barriers emerges. Identifying the stakeholders, their objectives and the barriers will help project implementation and project extension into real life.

Therefore, the following challenges need to be addressed:

- **Assessing urban logistics in cities:**
  - Urban freight KPIs and assessment models pursuing international standards (to ensure the quality, safety and security, social and environmental management, etc.) and benchmarking tools should be developed to define types of cities/districts, governance schemes and suitable solutions for specific cities/districts and situations.
  - Identify urban freight stakeholders, governance models and objectives of key actors and linking these to deployment barriers to innovative solutions (i.e. willingness to pay, etc.) and ways to overcome them.

- **Develop a framework for data collection to properly analyse urban freight movements in cities and their impact (structure of the sector, delivery characteristics, load factor, type of operations, relative share of different type of freight: retail, food, construction, maintenance and service vans, post, etc.), expected impact of home deliveries, etc.:**
  - Economic and behavioural modelling.
  - Urban freight transport demand/supply. Understand the trends of the freight transport demand and offer depending on the regulatory framework and megatrends: increasing e-commerce, increasing population in cities, increasing ageing population, effects of logistics sprawl (e.g. impact of decentralization of logistics facilities on transport movements, etc.) and how they influence the demand, its evolution and forecasting, its characteristics according to sector of activities, etc.
  - Explore further the potential gain from international cooperation between researchers, cities and industry on this topic.
• Analysing data and identifying opportunities:
  
  Data adequately acquired and structured is the basis for proper analysis and the source to identify opportunities for improvement. In this sense, potentially new urban logistics services may be identified, load factors increased and the effects of certain trends or measures anticipated.

  – Data collection methods and use for urban freight transport optimization.
  – Potential of new services associated to available data (big data).
  – Identify and demonstrate opportunities to increase the load factor.
  – Potential for improving procurement and benefit for joint procurement
  – Assess the potential impact of 3D printing on freight distribution, in particular in urban areas.

To increase the efficiency of urban logistics, it is necessary to engage all actors of the system. For this purpose, it is therefore necessary to understand the potential for cooperation between these actors, from the public and the private side, and to explore the frameworks which can create incentives for this cooperation.

Research in this respect should address the following topic:

• Understanding the potential for stakeholder cooperation including business models.

  Different interests of actors involved in urban logistics (local authorities, shippers, retailers and logistics service providers and consumers) need to be addressed to find commitments satisfying all of them. This topic refers to new collaboration formulas and concerted actions between actors, financing and governance structures, and new policies and regulation measures that benefit public and private parties. This would for instance provide relevant knowledge to identify solutions to address the challenge of so-called white vans including maintenance and service trips.

• Stakeholders awareness and involvement: New ways of collaboration and concerted actions between local authorities, shippers, retailers and logistics service providers, cooperative decision making and cooperative planning processes.

• Financing/Business models, roles, governance structure, supporting new services and cooperation

• Assessing the impact of policy regulation and frameworks:

  – Legal issues: urban public policy in the framework of the European competition law, single market versus access restriction
  – Translating public benefits to private: less congestion benefiting private business: incentives not to drive in peak hours and use of green vehicles.
  – Impact on freight of SUMP (Sustainable Urban Mobility Plans) implementation.

Policy initiatives have the potential to drive change in some cases and to encourage the deployment of efficient solutions from a system and collective perspective. It is however important to better understand the impact of public policies on urban freight. It is also important to identify the limits of public policy in the current European legal framework, and analyse concerns and implications of European competition law for cooperation and consolidation of goods deliveries.
**Impact:**
- Increase load factors.
- Reduction of freight vehicle movements.
- Increase effectiveness.
- Reduce congestion.
- Reduce environmental impact.

Towards a more efficient integration and management of urban freight in the transport system of the city

Achieving a cleaner and more efficient urban logistics system requires better integrating urban freight in the transport system and in the city. We should move from an activity which is trying to find a place in regulations and networks designed for other purposes towards an activity fully recognised and provided for.

The full integration of urban freight in the city therefore also depends on the evolution of the city and beyond of lifestyle.

Indeed, depending on the model of urban development and the development of trends such as teleworking or e-commerce, ageing society, the demand for passenger transport and goods transport may be complementary or antagonistic.

It should be taken into account that there is a relationship between the demand for passenger transport for certain type of activities, in particular work commuting, and the demand for goods transport.

Teleworking for instance reduces the demand for passenger transport but may increase the demand for shopping trips or home deliveries.

Home delivery itself, including e-Commerce, may replace shopping trips but increase travel for delivering goods. The relation between both should be better understood.

This touches upon issues such as land use and freight delivery, as well as the idea of accessibility. In this respect, considering the provision of transport for goods and consumers and their relation with other forms of transport, as suggested by the quadrants developed in the CAPIRE project, can help to understand these various factors.

8. Ecole des Mines for CAPIRE
Other transport activities within the city transport system may have an influence and being influenced by urban freight transport. Maintenance and service activities for example done by craftsmen are, to an extent, also goods (repair parts and damaged parts) transport and it could be useful to understand whether service and maintenance activities could be integrated within urban goods delivery or return and how.

Waste is another fundamental part of city transport. Can waste removal processes be integrated with the delivery or, more likely, the return of certain product categories?

Additionally, it is important to consider the relationship between tourism and urban freight. Tourism is a relevant economic sector in a high number of EU cities and its influence on both passenger and freight transport in cities, including potential seasonal scenarios, should be studied.

### 2.2.1 Towards a more efficient integration of urban freight in the urban transport system

The greater integration of urban logistics activities in the urban mobility systems requires furthering research and deploying solutions for **optimising the use of the road infrastructure in space and time for urban freight activities**. This includes exploring the potential for a more dynamic use of dedicated lanes and lane prioritizing, relying upon ITS when relevant. It also requires much work on exploring the potential for a more advanced management of parking spaces in relation to loading activities, addressing issues such as enforcement, up-scaling, business models and pricing.

The opportunities to differentiate the use of road space in time according to type of activities should also be further researched, with significant work required for innovation on better using road space at off peak hours and nights, considering the challenges related to business models, size and structure of consignees and constraints on operators. This may also involve the definition of service levels of the infrastructure.
This research on optimizing the use of the infrastructure should be complemented by investigations on how to use best the infrastructure for purposes different than the original ones.

The current urban road network was built with little considerations for logistics activities. The challenge is therefore today to assess how this same road space can be best used, also for this purpose.

This requires addressing questions such as the integration of urban freight with public transport on the road infrastructure, but also at the level of the vehicles and at public transport interchanges. The best use of these interchanges for urban freight delivery is a question to investigate for instance.

When it comes to the integration of different activities on the road infrastructure, research should aim to enable their integrated management at the strategic, tactical and real time level.

This means working on how to open bus lanes to other vehicles with a minimum impact on public transport operations and how to define the road transport infrastructure which can be available for freight activities. This should rely upon the knowledge which should be gathered on better understanding the barriers for this joint use of the infrastructure.

Lane prioritizing by the smart use of traffic lights depending on the type of traffic or the moment of the day requires also further research.

The potential impact and interaction of some policies, in particular related to access restriction and infrastructure charging, for both freight vehicles and passenger vehicles, requires also further understanding to move towards an optimised management of the infrastructure. This type of research should not only consider the public road infrastructure. It should also explore the potential of private infrastructures (parking, malls, etc.) and of infrastructure enabling the use of rail or water (lakes, rivers, etc.) for urban logistics.

While work is required on enabling this joint use of the infrastructure, it should be supported by activities building support for this among stakeholders. It should therefore be supported by work on public acceptance, and on the involvement of the different type of actors, in particular the freight operators.

It should be investigated to what extent and under what conditions some forms of public private partnerships can enable this.

Finally, the work should also address the challenge of integrating deliveries in the increasing number of infrastructure which are developed as shared space. Significant research is still needed to ensure that the best is made in the integration of urban freight in the urban mobility system, the development of tools and methods, including scenario planning and models, for fully taking urban freight into consideration at all stages of the sustainable urban mobility planning process. This should open for identifying opportunities to also assess the potential for using other modes and infrastructures than road for improving the urban freight system.

Considerations for passenger transport and urban freight transport should also enable to assess the opportunities for cross-fertilization of innovative and best practices between the two types of activities.
Figure 4: Towards a more efficient integration of urban freight in the urban transport system

**Impact:**
- Increase the number of available loading/unloading zones.
- Reduce the average number of kilometres per vehicle per delivery.
- Increase asset utilization.
- Reduce environmental impact.
2.2.2
Better understanding of the impact of land use on urban logistics activities

The better integration of urban freight in the urban transport network and beyond in the urban environment requires a better understanding of the impact of land use on urban logistics activities.

Research and innovation on this topic should help to increase the knowledge related to spatial patterns and urban freight facilities. It should lead to tools for measuring the role, location and impacts of warehouse, freight terminals and urban logistics platforms in metropolitan areas. On this topic, it is also necessary to assess and map locational trends and the impacts of «logistics sprawl» on freight flows, CO₂, local pollutants and congestion.

The location of logistics activities may also have an impact on the social cohesion of the territory and should be better understood.

Finally, some research should be carried out on measuring the accessibility of networks and terminals, for various types of actors. This should also cover public transport accessibility.

**Figure 5: Understanding the impact of land use on urban freight activities**

**Impact:**
- Increase the number of available loading/unloading zones.
- Reduce the average number of kilometres per vehicle per delivery.
- Create opportunities for the use of shorter-range, but more energy and emission efficient vehicles.
- Increase the load factor of vehicles.
- Properly locate the available loading/unloading zones.
2.2.3

Enabling a more efficient management of goods

Research focusing on the infrastructure dimension of urban freight activities should lead to managing the infrastructure to enable more efficient movement of goods in the urban environment. Connectivity and telematics solutions are enablers for many logistics and transport evolutions in the 21st century.

ITS to better manage the movement of goods

From access control and privileges granted to specific vehicles (low noise, low or zero emissions,...) to dynamic routing, lane sharing, load index control, information on other road users, delivery spaces availability or information related to logistics, ITS can offer a wide pallet of services that will improve the overall efficiency of goods distribution in Cities. However, the key focus of any research is to identify appropriate business models for technology adoption and market deployment.

The integration of urban freight in urban network management can rely on new improved traffic management operations and a better use of data on urban freight. This require to explore the potential of more exchange of data on urban freight, and of the possible deployment of C-ITS, in particular V2I.

To support this approach, research work should be carried on data definition/identification/collection/accessibility, for planning and policy and for urban freight plans. Models for data sharing and cost efficient data collection on urban freight should be considered. This requires also legal research related to privacy and competition issues. It should also involve the definition of incentives for exchanging data.

These activities should aim, among other things, at significantly improving the management of loading and unloading areas. It should enable a better enforcement of the regulations for their use, and of the information providing to drivers and operators to find and occupy them. Increased knowledge on how improved access to freight receivers and improved loading/unloading areas may contribute to improved efficiency and reduced emissions is also needed. This also influences future land use planning in cities.

Finally, the potential of e-Freight to accelerate this evolution towards a more efficient management of the network which better considers the movement of goods should be explored.
In-vehicle systems and connectivity

In the vehicle, the addition of messages and signals in an already overburdened mental environment must be carefully watched to propose specific solutions for information to be delivered safely and efficiently.

Regarding the vehicles, research supporting the development of ITS solutions for the efficient management of goods on the urban network should address the development of communication interface to manage all information related to vehicle operation, data exchange with infrastructure, data exchange with logistics operations, load management and mission profile.

The target should be a step by step market introduction of these vehicle developments between 2020 and 2025.

The limit of the scope of the roadmap regarding the vehicles is also defined by the scope of the European Green Vehicles Initiatives. ERTRAC/EGVIA focus on electrification of road transport and on heavy duty trucks mainly for long distance transports. The content concerning research needs for urban applications are limited beyond the more obvious carry over effects from alternative driveline research activities.

Figure 6: Enabling more efficient movements of goods through the management of the infrastructure

Impact:
- Reduce the number of km per vehicles per delivery.
- Increase the load factor of vehicles.
- Increase the rate of available loading possibilities.
2.2.4

Improving the interaction between long distance freight transport and urban freight

Increasing the efficiency of urban logistics requires improving the integration between networks and operations, including improving the interaction between long distance freight transport and urban freight.

This research topic covers the interface and interactions with long distance freight transport services and infrastructures (airports, seaports, intermodal terminals, dry ports, logistics platforms, etc.).

In long distance freight transport, efforts to increase efficiency and make the transport more sustainable often lead to scale increases, such as the use of Longer and heavier vehicles or mega vessels, and a more diversified use of transport modes. On the other hand, within many European cities a downscaling of transport modes used for urban deliveries, such as cargo bikes, is witnessed to decrease the nuisance. A major challenge therefore is the coordination of these very different trends. It for instance raises the question of optimising the management and location of long time parking places for trucks in or around urban areas.

In this regard, the Physical Internet concept in which logistics and supply chain networks are open and integrated including warehouses and hubs should enable proper consolidation of freight transport in the last mile delivery in urban areas.

Additionally, space for temporal storage is often required, which is not easy in an urban setting where space is limited and expensive. A major role is reserved for intermodal transhipment locations and different types of consolidation centres. Those can include for instance concepts of mobile depots.9

It should include studies on land use and freight transport/logistic operations interaction, and the impact of the multiplicity of logistics hubs and networks. This should lead to developing solutions for optimising the use of postal/small parcel hubs/infrastructure in cities. It could also help designing freight corridors in cities / regions, including the intention of providing for a better management of long distance freight transport going through the urban transport network. Special attention should be paid to the possibilities of establishing publicly controlled consolidation centres operated by private companies.

Besides, new trends in long distance transport such as the increasing alignment of different transport services as in e.g. synchromodality, necessitates additional alignment with the transport activities in the city centre.

The multimodal dimension of freight transport should be considered in this topic, for instance for optimizing the use of inland ports and develop the use of intermodal terminals and freight villages, as well as the link between interregional and local transport flows.

**Figure 7: Improving the interaction between long distance freight transport and urban freight**

**Impact:**

- Reduce the average number of kilometres per vehicles.
- Optimise the network of consolidation/transhipment centres.
- Allow the use of electric vehicles for last mile deliveries.
2.2.5
Better adapting the vehicles to innovative urban freight delivery systems

The better integration of urban freight activities in the urban transport system also requires developing innovative vehicle solutions better fitted, through flexibility and modularity, to innovative urban freight delivery systems.

Trucks and vans operations suffer from - and participate to- congestion, even if they represent a minor part of the overall traffic. Vehicles stopped in traffic jams, driving unwanted kms to find a place to park, represent a major lack of efficiency for transport companies as well as for the other road users, blocked by vehicles stopped to deliver goods. Double parking as a quick solution for a faster delivery creates traffic problems which severely affect the quality of service of other public or goods-related transports and stress drivers in private vehicles.

Improving the overall efficiency of the system, to decrease its impact on congestion means decreasing the unwanted miles driven, the unnecessary stops and the time wasted accordingly. To address this challenge, the following topics should be addressed:

- Define future optimal urban freight vehicle sizes and architectures from multi-stakeholder perspective.
- Work on developing innovative alternative vehicles, such as cargo bikes, should continue to be supported.
- Develop loading rate measurement systems (weight, volume...), to be linked with overall city access control and network management.
- Develop standardized and modular logistics units (compatible with regular containers) for a better load factor and interoperability among different transport systems and modes.
- Develop technologies to transfer loads between vehicles (large and smalls) as well as with other transport modes (holistic multimodal approach) (architecture of vehicles, load units...) to allow a decoupling of the delivery processes between mass transport and last mile operations.
- Lowering the noise related to handling, loading and unloading of the goods to enable night deliveries.
- Facilitate access to delivery areas: semi-automation / automation of vehicles (Vehicle manoeuvrability and driver assistance)

The first step will consist in the development and provision of increasing driver support, which will be followed by semi automation.\(^\text{10}\)

\(^{10}\) The automatisation of vehicles will be adressed in a separate ERTRAC initiative
Figure 8: Better adapting the vehicles to innovative urban freight delivery systems

**Impact:**
- Increase the load factor of vehicles.
- Reduce the number of km per vehicle per delivery.
- Increase the availability of loading and unloading areas.
- Enable night freight deliveries.
2.3

Business models and innovative services

Research and development on new business models associated to the smart urban logistics needs to answer economic, environmental and social aspects allowing growth and industry to run their business and at the same time guaranteeing wellbeing for citizens.

2.3.1

Value creation logistics services and more efficient operations

Supply chains evolve quite rapidly, adapting their service specifications to constant changes in consumers and clients’ requirements while taking advantage of opportunities for improved efficiencies offered by new technologies. In order to fully optimise the efficiency of most supply chains, a better look has to be taken to the final delivery of goods which is done in urban environments. Traditionally, due to lack of resources or local knowledge or pure cost issues, the last mile delivery has been outsourced to specialized companies (mail or express companies, local agents, etc.) and, somehow, direct control of the physical operations is lost or, at least, handed to someone else. The shift in consumer trends towards e-commerce and the current demand for better environment conditions in cities urges to look deeper into this part of the supply chain trying to find new ways to improve efficiency in a context where local regulations have a big influence on the results to be obtained. New types of services and new ways of performing the operations are areas to be explored under this topic.

Considering the ever growing fragmentation of orders, particularly at final delivery point, a trend reinforced by e-Commerce. A look into consolidation schemes and models to increase the load factor while considering the urban supply chain, is mandatory if freight traffic is to be reduced.

This requires considering business models for consolidation schemes, including fleet and freight sharing and pooling. Research should also address new concepts for the design of distribution centres in cities for last-mile distribution (e.g. cross-docking methodologies), and the impact on the optimal utilisation of the infrastructure.

A better use of land space is also required considering the scarcity and high costs of urban land. Sharing vehicles and infrastructures, however, is not a straightforward task, since several issues have to be tackled, including common ICT infrastructures, sharing of critical information related to clients and internal processes, service compliance with different service requirements, cost sharing, etc. Collaboration between operators/supply chains/shippers, load factors, competitions challenges should be investigated.

This degree of sharing translates into new opportunities for collaboration across the supply chain and among competitors.

Other logistics models, specific for urban distribution (night distribution) need further analysis to find ways to extend it to smaller business and not-dedicated supply chains. Efforts are needed to further develop solutions for out of office hours delivery strategies to retail, and for specific logistic chains such as HORECA (hotels – restaurants-cafes). This requires to improve the measurement of opportunities and to provide night deliveries technology for all business, including, for instance, small shops. This may involve developing simultaneously for solutions and opportunities for consolidations for the same target group of businesses.
ICTs can be a critical tool in this context, enabling data sharing and data integration, which should also be considered across the different supply chains.

In this respect, research should explore the potential of the Internet of Things and Future Internet for logistics. It should, in particular, investigate measures to improve and maximize the availability and (cross-border/cross-system) interoperability of transport data and information systems. This involved studying the definition and monitoring of data quality, while considering data security and integrity related challenges.

There is a need for further work on improving current freight models and the better integration of urban freight in main traffic models. The goal should be to move towards real-time information exchange; highly accurate, dynamically updated maps and positioning systems.

Together with C-ITS for instance, this should enable green driving support systems.

There is also a challenge regarding packaging in the last mile distribution, in particular around fresh, refrigerated and frozen goods. Reverse logistics associated to this packaging is also an issue which needs to be tackled with the view of minimizing waste and optimizing reverse flows.

The optimization of load units could contribute to this effort, with the optimization, modularisation and standardisation of packaging and load units for business and home deliveries.

The packaging and delivery of fresh product should be researched specifically, as they represent a significant shares of the goods transported on the urban network.

Finally, the potential for deploying further certification schemes in urban logistics, further developing approaches such as Lean & Green for instance, should be investigated as it could support the freight operators to move towards TQM for continuous improvement.
Urban Freight Research & Innovation Roadmap

Figure 9: Value creation logistics services and more efficient operations

**Impact:**
- Increase load factors.
- Increase asset/infrastructure utilization.
- Reduction of freight vehicle movements.
- Increase of first time delivery.
- Increase customer satisfaction.
2.3.2 e-commerce implications: Direct to consumer deliveries and functional logistics services

E-commerce is becoming the new paradigm in retailing. Beyond being a new channel of sales for retailers, the internet gives the consumer a new power to influence what is sold and how. Consumers have now a soft, easy way of accessing products avoiding physical travelling to shops and this gives a new opportunity for acquiring goods to shoppers with limited mobility (ageing or sick people, for example; people living far away from shopping areas; youngsters or people without a private car,…). The problem with e-commerce is that it multiplies the number of deliveries since trips saved by consumers have to be done by the commercial vehicles. Also, there is a total dispersion of delivery points and an additional difficulty in planning the times for delivery which have to adapt to each different shopper. Returns, as frequent as 50% of purchases in clothing and textiles in some countries, for example, add to the dimension of the problem. Logistics operations for e-commerce have different requirements and solutions than those for traditional retailing, but research is needed to obtain a better insight of the problems and possible solutions to apply.

Figure 10: Forecast. European Online Retail Sales By Country, 2012 to 2017
Specific logistics models for e-commerce which resolve the problem of the delivery to the final customer (do it right at the first time) have to be analysed and their impact in terms of cost, service, space use and environment have to be measured. In that field, solutions for the efficient management of home deliveries need to be developed. They involve for instance multiuser-multiprovider pick-up point stations. But further solutions can be researched in decoupling delivery and reception. Research should for instance cover flexible pick-up points networks (offices, public transport hubs, parking, neighbourhood retired people, private and public vehicles, etc.). Such flexibility gains would have impacts on costs, sustainability, payment schemes and delivery times that have to be investigated.

New types of shops, show rooms etc. in urban areas due to e-Commerce could also affect the distribution patterns within the urban area. There may be less need for products in the shops or the opposite depending on structure of supply chains.

Finally, the quality of the service should be better understood, for instance the difference between the service as it is done and as it is perceived (requirements, traceability, etc.) or the social benefits of such a system, which marks the emergence of a new urban freight paradigm.

The integration of click-and-mortar distribution channels should also be researched.

**Figure 11: E-commerce implications: Direct to consumer deliveries and functional logistics services**

**Impact:**
- Maintain/Increase load factors.
- Reduction of private vehicle movements.
- New business opportunities increasing employment.
- Increase of first time delivery.
- Increase customer (including ageing) satisfaction.
2.3.3 Reverse logistics and transport of waste and recycling material

Cities are facing an increasing volume of waste, recycled material and returns (from e-commerce for example) that needs to be managed. This topic focuses on the analysis of niches and opportunities to integrate direct and reverse flows, and the research on new integrated logistics models to increase the global efficiency.

Flows that currently work separately could be optimized if opportunities for synergies are identified and new business models developed. Reverse logistics associated to e-commerce have also to be considered for this potential flow integration. It is therefore necessary to research the following questions related to reverse logistics and the transport of waste and recycling material:

- Measuring trends for direct and reverse volumes: implications of e-commerce.
- Current vs new paradigms and business models of direct and reverse flows (recycling and returns).
- Direct and reverse logistics models, integration and cargo pooling: empty runs avoidance.
- Logistics management models in an increasing recycling society urban environment.
- Combining flow waste from industry (construction material and the others) and domestic.

Impact:
- Increase load factors.
- Increase asset/infrastructure utilization.
- Reduction of freight vehicle movements.
- Increase customer satisfaction.
- New business opportunities increasing employment.
- Improve urban transportation policies.
2.3.4 Designing and operating urban freight delivery infrastructures

This research topic focuses on better understanding how to best build and manage infrastructures dedicated to freight delivery in the urban environment, such as loading/unloading areas, consolidation centers, pick up points, warehouses, etc. It covers issues such as the use of brown fields for urban freight deliveries, or the architectural design and integration of logistic facilities in urban areas, as well as the business models supporting them. This would involve studies on the design and architectural issues related to freight facilities in cities. It should help to develop tools to support industrial brownfields for urban logistics spaces. Researching the improvement of freight infrastructure should also include research on the vertical exploitation of space. To what extent can verticality be interesting for goods storage and transport?

This topic also includes all research activities specific to the building, financing and operation of the facility. This covers financing and business models for building and operating the facility, and the research for greater efficiency in the management of the infrastructure, for different purposes, different logistics chains, and at different times of the day.

Finally, the design and operation of freight infrastructure also covers the integration of this infrastructure with other type of infrastructures and building, for instance in the framework of greenfield development. This is related, among other things, to the better integration of the freight dimension in the planning of urban infrastructures in general.

The scope could include the definition and research on the requirements, conditions, needs, etc. for a preferential use of the infrastructure by clean vehicles (timetable – wider range for the use of the infrastructure, supports, etc.).

Figure 13: Designing and operating urban freight delivery infrastructures

Impact:
- Increase the load factor of vehicles.
- Reduce the average number of km per vehicles.
- Reduce the environmental impacts of logistics buildings.
2.4 Safety and security in urban freight

The security of freight and freight operations in the urban environment remains a challenge in too many cases. A significant amount of goods is lost following security breaches. It is therefore important to identify solutions to guarantee a safe urban delivery system minimizing the risk for the freight operators. Research efforts should be extended to systems enabling the decoupling of the delivery and the collection of the goods, such as pack stations, in vehicles delivery, etc. These systems will only deliver their full potential if they are proven and perceived as safe and reliable by the citizens.

To achieve the objective of reducing by 90% the amount of goods lost or stolen, research should cover the following topics:

- Affordable technology/processes to achieve load unit traceability and visibility.
- Locks and seals to guarantee vehicle integrity.
- Secure and reliable automated parcels lockers and delivery units.
- Increasing integrity of goods (perishable, electronic, high value).
- The opportunity to extend the ecall system to provide drivers with a reliable tool for declaring a theft in progress with risk to their personal integrity.
- Automated monitoring of surrounding traffic with software capable of identifying potentially threatening behaviours from other vehicles.

Delivering goods in cities may lead to safety concerns for vulnerable road users (VRU) as well as for the driver. There is indeed a high share of accidents of vulnerable road users involving commercial vehicles in the urban environment. This is due among other things to the lack of visibility of VRUs in the urban environment when driving and manoeuvring. Tail lift use can be dangerous for pedestrians and cyclists. Leaving the cab and manipulate packages, pallets close from heavy traffic is risky for the driver.
Research should therefore address the following additional topics on road safety and driver security in traffic:

- Driver support and visibility equipment for a 360° safety around the vehicle when driving and manoeuvring.
- Include messages to vulnerable users, communication via lights, beeping sounds when backing up as in heavy duty vehicles, also when operating tail lifts...
- On a longer term, assess the opportunity to separate “virtually”, dynamically commercial vehicles from vulnerable road users.
- Vehicle architecture for a safe and easy entry /exit as well as load handling (to be considered taking into account the variety of usages and the affordability of solutions), including goods security when delivering.
- Risk analysis and research for some specific supply chains (constructions).
- Assessment of the opportunity for integrating road safety measures in urban freight policies.

Working on vehicle architecture for safety purposes can as well integrate the conditions for a better public acceptance of delivery vehicles, through an enhanced integration in the city landscape while maintaining or even improving the efficiency attributes of delivery vehicles; (design acceptance, VRU protections, no visible moving parts...)

**Impact:**
- Reduce cargo lost or damaged.
- Reduce accidents involving vulnerable road users.
The scope of this roadmap regarding research and innovation on vehicles includes all types of vehicles, used to transport and deliver goods. These are mainly vans and trucks.

The main size of the vehicles is 3.5 tons (gross vehicle weight...) for vans up to 26 tons rigid trucks (global deliveries and refuse collection), even 32 tons rigid trucks for construction. Semi-trailer and / or truck + trailer are also used in lower volumes.

This chapter focuses on trucks, as 3.5 tons vans are a different market.

Decreasing the number of km driven thanks to more efficient organizations (see § congestion) participate to a positive evolution. But cleaner and more efficient vehicles can enhance further the positive trend to fuel consumption reduction and an improved urban environment.

It is therefore necessary to carry further research:

- Developing alternative fuels proposals (incl. electricity) with direct cost/life cycle cost and overall system business model as a target. Fuel availability and distribution, considered in the framework of the business model, to build a comprehensive deployment model, must be addressed.

- Integrate management of vehicle auxiliaries for a wider scope of implementation (e. g. for loading systems, pumps, tippers, refuse vehicles...).

- Develop alternative fuels proposals for autonomous body modules (refrigerating unit, street sweepers...).

- Investigate the second hand market of alternative fuel vehicles and their impact on the residual value of the vehicle. The same could be done for batteries of electric vehicles.

- Making eco-driving easy for drivers.

- Further research the reduction of particulates from brakes and tires.

- The deployment of a charging infrastructure for electric freight vehicles operating in urban areas (cargo-bicycles, two wheels vehicles, etc.), the integration of this infrastructure and of the charging in the management of freight vehicles, and the business model supporting the use and financing of these vehicles and the charging infrastructure.

- Developing new materials for vehicles improving the characteristics of the vehicles (less weight, resistance, etc.).

Besides air pollutants, vehicles impact also the urban environment with noise emissions. Noise is one of the most harmful pollutants impacting citizens in a city, as this has been confirmed for instance by the World Health Organisation. Therefore, the reduction of vehicle noise is an important research priority. Also, the reduction of vehicle noise is a condition for shifting deliveries to off-hours.
Deliveries early in the morning, or during the evenings (even at nights in some cases) leads to specific requirements for low noise concepts, following the early implementation of the Dutch “Piek” principles (a certification scheme and technology development programme for vehicles and equipment operating under 60dB).

Research topics:

- Definition of a EU standard methodology for noise measurement for the overall delivery process.
- Development of “affordable” low noise solutions (not only EV vehicles) including full vehicle equipment (truck/van body, lifting/loading equipment,…). This is to be linked with overall city access control and ITS management.

Impact:
- Reduce the emissions of pollutants from the vehicles.
- Increase the energy efficiency of the vehicles.
- Increase the availability of loading and unloading areas.
- Reduce the noise of urban freight.
- Enable night distribution.

<tr>
<td>SUPERGREEN</td>
<td>Supporting EU's Freight Transport Logistics Action Plan on Green Corridors Issues.</td>
<td>The purpose of SuperGreen is to promote the development of European freight logistics in an environmentally friendly manner. Environmental facors play an increasing role in all transport modes, and holistic approaches are needed to identify ‘win-win’ solutions. SuperGreen will evaluate a series of ‘green corridors’ covering some representative regions and main transport routes throughout Europe.</td>

<td>TRAILBLAZER</td>
<td>Transport and innovation logistics by local authorities with a zest for efficiency and realisation.</td>
<td>TRAILBLAZER aims to showcase existing good practices and promote public sector policy interventions which can bring about a reduction in energy used in urban freight transport. This will be achieved by municipalities, in partnership with their suppliers and the private sector through the implementation of Delivery and Servicing Plans (DSPs).</td>
<td>January 2012-June 2013</td>

<tr>
<td>UrbanZen</td>
<td>InnoVative Flexible Electric Transport.</td>
<td>UrbanZen offers a centralised, collaborative solution to help free up the urban traffic of heavy goods vehicles. It is based on centralising geographical information coming from the drivers and the municipal authorities. This solution is designed to establish the existence of congestion hotspots for carriers and incorporate them into mobility policies implemented by municipal authorities. Information is passed on to the drivers via GPS so they can automatically change their route by calculating an alternative itinerary to suit the restrictions communicated by authorities.</td>
